

# Structured Programming

## - Recursion

Donglong Chen

Structured Programming

With **Thanks** to Dr. Xin Feng and Dr. Haipeng Guo

# Outline

- Recursive call of functions
- Examples
- Recursion and iteration

# Dominoes

How do dominoes work?

Structured Programming

# Dominoes

- The  $n$ -th card is pushed by the  $(n-1)$ -th card (recursive step)
- To make the dominoes work, the 1st card must be pushed first (base case)
- This is called recursion

# More Examples of Recursion

- A recursive definition of person's ancestors
  - One's **parents** are one's **ancestors** (**base case**).
  - The parents of one's ancestors are also one's ancestors (**recursive step**).
- Natural numbers
  - **0** is a natural number (**base case**).
  - if **n** is a natural number, then **n+1** is also a natural number (**recursive step**).

# Recursive Functions

- A recursive function
  - calls itself
  - uses different parameter values
  - stops calling itself when the base case is met
- Recursive functions are commonly used in the applications in which the **solution to a problem** can be expressed in terms of **successively applying the same solution** to subsets of the problem
- The famous factorial calculation problem
  - $n! = n * (n-1) * (n-2) * \dots * 1$
  - $n! = n * (n-1)!$  and  $1! = 1$   
recursive step                      base case

# An Example – Factorial Number

Recursive step: the result of `fac(n)` is `n * fac(n - 1)`

Base case: `fac(1)` is 1

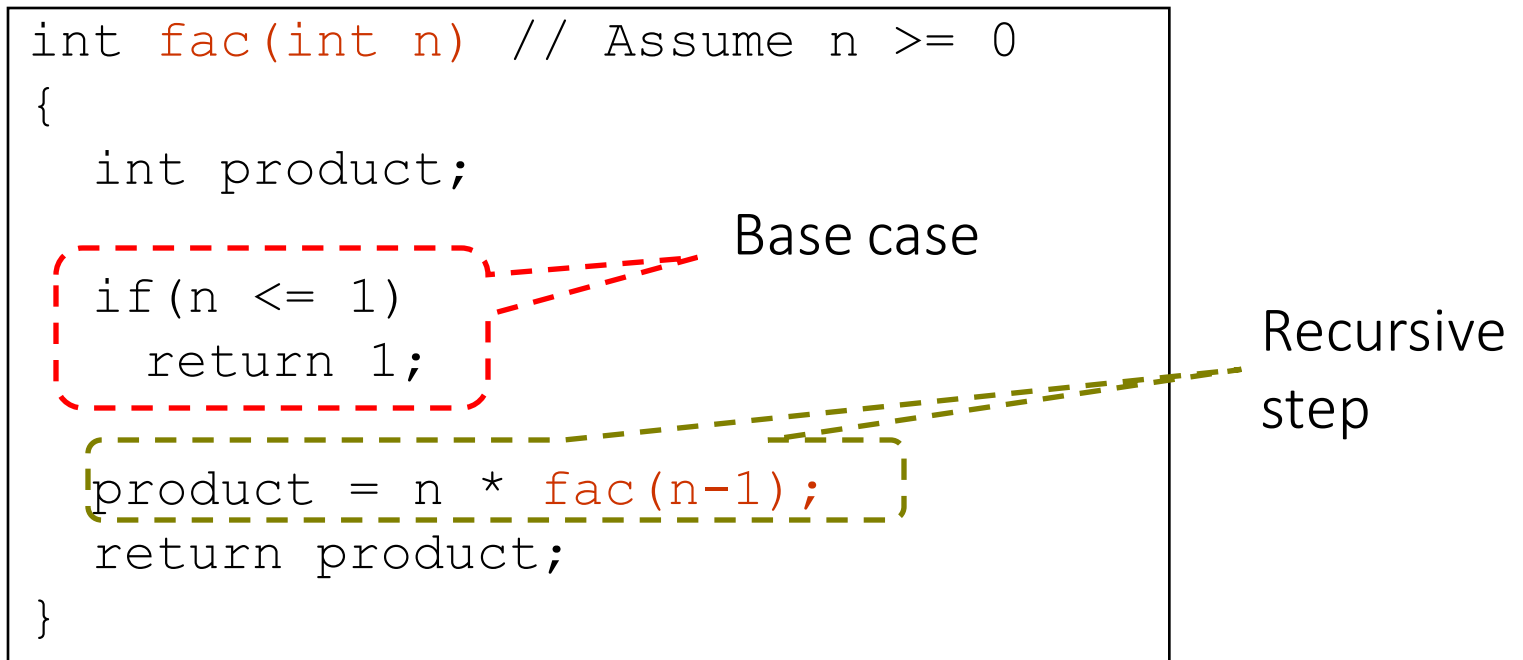

```
int fac(int n) // Assume n >= 0
{
    int product;

    if (n <= 1)
        return 1;

    product = n * fac(n-1);
    return product;
}
```

Base case

Recursive step

A diagram illustrating the components of a recursive factorial function. The code is enclosed in a black rectangular box. A red dashed rectangle highlights the base case: 'if (n <= 1) return 1;'. A red dashed line points from the text 'Base case' to this highlighted section. A green dashed rectangle highlights the recursive step: 'product = n \* fac(n-1);'. A green dashed line points from the text 'Recursive step' to this highlighted section.

# An Example – Factorial Number

- Assume in main program, we use fac(3) to call the fac function

```
int fac(int n)
{
    int product;
    if(n <= 1)
        return 1;
    product = n * fac(n-1);
    return product;
}
```

```
int main()
{
    .....
    r = fac(3);
    .....
}
```

**fac(3) :**

3 <= 1 ?

product = 3 \* fac(2)

**return product**

**fac(1)**

1 <= 1?

**return 1**

**fac(2) :**

2 <= 1 ?

product = 2 \* fac(1)

**return product**

# Base Case

Base case is also called stop condition

# Another Example

- Write a recursive function **zeros** that counts the number of zero digits in a non-negative integer. E.g., `zeros(10200)` returns 3

What is the **base case**?

How to express the **recursive step**?

# Another Example

One digit:

0: return 1

others: return 0

More digits:

rightmost digit 0: return 1 + number of zeros  
in the rest digits

rightmost digit others: return 0 + number of  
zeros in the rest digits

```
int zeros(int n)
```

```
{
```

```
    if (n == 0)
```

```
        return 1;
```

```
    if (n < 10)
```

```
        return 0;
```

Base case (stop conditions)

```
    if (n % 10 == 0)
```

```
        return 1 + zeros(n / 10);
```

```
    else
```

```
        return zeros(n / 10);
```

Recursive step

```
}
```

# Another Example- Fibonacci numbers

- Fibonacci numbers:

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, ...

where each number is the sum of the preceding two. Write a recursive function to solve this.

What is the **base case**?

How to express the **recursive step**?

# Another Example- Fibonacci numbers

Base case

```
int Fibonacci(int n)
{
    if(n == 0)
        return 0;
    if (n == 1)
        return 1;

    return Fibonacci(n - 2) + Fibonacci(n - 1);
}
```

Recursive step

# Another Example- Factors

- Write a recursive function to determine how many factors  $m$  are part of  $n$ . For example, if  $n = 48$  and  $m = 4$ , then the result is 2 (since  $48 = 4 * 4 * 3$ ).

What is the **base case**?

How to express the **recursive step**?

# Another Example- Factors

Base case

```
int factors(int n, int m)
{
    if(n % m != 0)
        return 0;

    return 1 + factors(n / m, m);
}
```

Recursive step

# Writing a Recursive Function

- Three steps
  - Find the base case
  - Find the recursive step
  - Write the recursive function

# Recursive Function

- A recursive solution may be simpler to write (once you get used to the idea) than a non-recursive solution.
- But a recursive solution may not be as efficient as a non-recursive solution of the same problem.
- Each recursion call consumes some memory.

# Recursion and Iteration

- Recursion is based upon calling the same function successively
- Iteration simply 'jumps back' to the beginning of the loop
- A function call is often more expensive than a jump

```
int fac(int n)
{
    int j;

    product = 1;
    for (j = 2; j <= n; j++)
        product = product * j;
    return product;
}
```

Use iteration to  
implement factorial  
number

# Class Exercise

- Can we can solve the following questions with recursive functions? If yes, please give the base case and recursive step.
  - Calculate sum of a sequence numbers in an array.
  - Sort a sequence of numbers stored in an array.
  - Print the following pattern (Number of lines is determined by the user input).

\*\*\*\*\*

\*\*\*\*

\*\*\*

\*\*

\*

# Summary

- It is important to find the relations in the recursion functions.
- Using recursion can make programming simpler.
